

Name : ARUL

Roll Number : CS005

PART - A

Q1

Encapsulation means combining data and functions inside a class. It is used to hide data from outside users.

Q2

Inheritance is when a class gets properties from another class. It reduces re-writing code.

Q3

A destructor is a function that is used to destroy an object when it is no longer needed.

Q4

Polymorphism

Polymorphism means one thing can take many forms. There are different types of polymorphism in C++.

Q5

Abstraction means showing only important details and hiding unnecessary implementation details from the user.

PART - B

Q6

Inheritance is a feature where one class use properties of another class. It helps in reducing code.

Example:

```
class Animal { public: void eat() {} };  
class Dog : public Animal { }  
The Dog class can use the eat() function from Animal.
```

Inheritance also improves security because private variables cannot be accessed from outside the class.

Q7

Encapsulation combines data and methods together inside a class

Advantages:

1. Data hiding
2. Security
3. Reusability of code
4. Parent class properties can be reused in child classes

Example:

```
class student {
```

```
    private:
```

```
        int mark;
```

```
    public:
```

```
        void
```

```
        set mark (int n) {
```

```
            mark = n; }
```

Q8

[illegible]
